

The selnolig package: Selective suppression of typographic ligatures^{*}

Mico Loretan[†]

2013/08/25

Abstract

The selnolig package suppresses typographic ligatures selectively, i.e., based on predefined search patterns. The search patterns focus on ligatures deemed inappropriate because they span morpheme boundaries. For example, the word `shelfful`, which is mentioned in the `TeXbook` as a word for which the `ff` ligature might be inappropriate, is automatically typeset as `shelfful` rather than as `shelfful`.

For English and German language documents, the selnolig package provides extensive rules for the selective suppression of so-called “common” ligatures. These comprise the `ff`, `fi`, `fl`, `ffi`, and `ffl` ligatures as well as the `ft` and `fft` ligatures. Other `f`-ligatures, such as `fb`, `fh`, `fj` and `fk`, are suppressed globally, while making exceptions for names and words of non-English/German origin, such as `Kafka` and `fjord`.

For English language documents, the package further provides ligature suppression rules for a number of so-called “discretionary” or “rare” ligatures, such as `ct`, `st`, and `sp`.

The selnolig package requires use of the `LuaATeX` format provided by a recent `TeX` distribution, e.g., `TeXLive 2013` and `MiKTeX 2.9`.

^{*}Current version: 0.255. Features of the selnolig package are subject to change without prior notice.

The main text font used in this document is Garamond Premier Pro. EB Garamond is used for words that use the `fb`, `fh`, `fj`, `fk`, `ffb`, `ffh`, `ffj`, `ffk`, *es*, and *se* ligatures. “Common”, “discretionary”, and “historic” typographic ligatures are enabled for these text fonts—and are suppressed selectively using the rules of the selnolig package.

1 Introduction

The ability of T_EX and Friends to use typographic ligatures has long been cherished by its users. Indeed, the automated and transparent use of typographic ligatures by T_EX and Friends is often offered up as one of the reasons for using these programs to obtain high-quality typeset output.

However, even though the automatic use of typographic ligatures is highly desirable in general, there are words for which the use of certain typographic ligatures may not be appropriate. The T_EXbook observes, on page 19, that the word `shelfful` may look better if it is typeset as “shelfful”, i.e., *without* the `ff`-ligature, rather than as “shelfful”. Some other English-language words that would generally be considered to be good candidates for non-use of ligatures are `cufflink` and `offload`; compare their appearance with that of `cufflink` and `offload`. Observe that all three of these words are composed of two meaning-bearing particles or *morphemes*: the first morpheme ends in an “f” or “ff” while the second morpheme starts with either an “f” (in the case of `shelfful`) or an “l” (in the cases of `cufflink` and `offload`). A *morpheme*, briefly stated, is the smallest linguistic unit within a word that bears distinct meaning; all words—other than nonsense words, I suppose—contain at least one morpheme. The words `apple` and `orange` contain one morpheme each, and the words `apples`, `oranges`, `shelfful`, `cufflink`, and `offload` each contain *two* morphemes. The main purpose of the `selnolig` package is to provide methods and rules for an automated yet selective (rather than global) suppression of typographic ligatures that span certain morpheme boundaries.

For English language documents, the need to suppress typographic ligatures that span morpheme boundaries does not appear to be a hugely pressing typographic concern, possibly because English doesn’t feature composite words that frequently. However, in other languages, such as German, composite words are much more common. In these languages, there is naturally a much greater potential for composite words to feature instances of `ff`, `fi`, `fl` etc. character pairs that span morpheme boundaries. In German typography, a ligature that spans a morpheme boundary appears to be something that should be avoided at (nearly) all cost, presumably because the presence of such ligatures has the potential to impair seriously the intelligibility of the composite words.

T_EX and Friends offer several methods for suppressing ligatures on a case-by-case basis. In L^AT_EX, there are three basic methods for suppressing ligatures: (i) insertion of an “empty atom”, `{ }`, between the characters whose ligature should be avoided; (ii) insertion of an explicit italic correction, `\/`; and (iii) insertion of an explicit “kern”, e.g., `\kern0pt` or `\hspace{0pt}`.¹ The `babel` package, when used with the `ngerman` or `german` options, offers the “shortcut” macro `"|` to suppress ligatures. A drawback of these ligature suppression methods is that they must be applied separately to each and every occurrence of all words that contain unwanted ligatures. As such, these case-by-case methods are both time-intensive and tedious. Moreover, there’s always a residual risk that some words for which ligatures should be suppressed will be overlooked in the editing process.

There are also several preprocessor-type packages and scripts—I mention `rmligs` and `Ligatures-German` in [Section 7](#) below, but others exist as well—that scan the input file(s) and insert marks (usually, but not necessarily, the `babel` `"|` shortcuts) in the places where ligatures should be avoided. While ingenious, these preprocessor-based solutions suffer from several drawbacks which, taken together, may help explain why

¹Note, though, that the first ligature suppression method, `{ }`, does *not* work if the document is compiled with Lua^L_AT_EX, and that the italic-correction method can produce inferior results if the text is being typeset in, well, the italic font shape.

they do not appear to be in widespread use. First, they add complexity to the document preparation process; e.g., the input files may have to be closed prior to running the preprocessor scripts on them, and then the files have to be re-opened in order to recompile them. Second, AFAICT none of the ligature-suppressing preprocessor packages (at least not the ones I’m familiar with) have been written to handle the needs of English language texts. Third, their scope generally seems to be limited to the most basic f-ligatures (ff, fi, fl, ffi, and ffl); extending them to treat further f-ligatures such as ft and ffit, let alone “rare” ligatures such as st and sp, would appear to be a nontrivial undertaking. Fourth, and maybe most seriously, they usually require access to auxiliary programs (e.g., a UNIX environment and a perl distribution in the case of the rmligs package) that need not be present on a given user’s computer.

What has *not* been available so far is a L^AT_EX package that (a) provides a list of language-specific word patterns for which ligatures should be suppressed and (b) systematically discovers all instances of these patterns in a document and applies the non-ligation rules at compilation time to all words for which one or more pattern matches occur. The selnolig package is meant to address this need. The package provides extensive lists of ligature suppression rules tailored to both English and German language documents.²

The selnolig package provides rules to suppress *selectively* the following f-ligatures, for both English and German documents: ff, fi, fl, ffi, and ffl—the “standard” f-ligatures that should be familiar to most users of Computer Modern fonts—as well as the ft and ffit ligatures. The latter two ligatures, while not provided by the Computer Modern and Latin Modern font families, are frequently available in `oldstyle` (also known as “Garalde”) font families.³ Oldstyle-type font families generally feature a great variety of typographic ligatures. Given the popularity of these font families for typesetting, the selnolig package provides ligature suppression rules for many of the ligatures provided by these font families.

For both English and German language documents, the ligatures fb, fh, fj, fk, and *ij* are suppressed *globally*; see also [Section 5.5](#). However, exceptions are provided in order not to suppress these ligatures for selected words of *non-English/German* origin, such as fjord, fjell, Prokofjew, Kafka, and *rijsstafel*.

For English language documents, the selnolig package recognizes an option called `broadf`; if it is set, additional f-ligatures will be suppressed selectively. And, if the package’s `hdlig` option is set, selective ligature suppression is performed on discretionary/rare ligatures such as ct, st, sp, *sk*, *th*, *at*, *et*, *ll*, *as*, *es*, *is*, and *us*. No rules are currently provided to suppress historic and/or discretionary/rare ligatures for German documents.⁴

The selnolig package also provides supplemental hyphenation exception lists for both English and German language words. The words in these lists are generally composite and contain one or more typographic ligatures that should be suppressed.

²Of course, no claim as to the completeness of either list is or can be made. Hence, the selnolig package also makes it straightforward for users to provide their own, supplemental, ligature suppression rules to treat words that occur in their documents but aren’t yet covered by the package. Please feel free to email me such words, so that I can augment and update the package’s ligature suppression rules suitably. A suggested template for reporting issues with the selnolig package is provided in [Appendix F](#).

³In some oldstyle font families, the ligatures “ft” and “ffit” are rendered as “ft” and “ffit”, respectively.

⁴A quick remark on the classification of typographic ligatures in OpenType fonts: There appears to be little or no standardization across fonts as to which typographic ligatures should be labelled “historic” and which ones are labelled “discretionary”/“rare”. For instance, the fonts Latin Modern Roman, Garamond Premier Pro, and Hoefler Text report having “only” discretionary ligatures, in contrast, the fonts Juniceur, Cardo, EB Garamond, and Palatino Linotype all report having both historic and discretionary ligatures.

The remainder of this document is organized as follows. [Section 2](#) provides instructions for loading the `selnolig` package and making one’s document(s) suitable for compilation under Lua^ATeX. The package’s overall approach to the suppression of ligatures that span morpheme boundaries is explained in [Section 3](#), the user macros are presented in [Section 4](#), and options that affect the package’s workings are discussed in [Section 5](#). [Section 6](#) addresses further issues that may arise when looking to break up typographic ligatures. The package’s ligature suppression rules for English and German language documents are listed in [Appendices A](#) and [B](#). The code of the package’s main “style” file, `selnolig.sty`, and Lua code file, `selnolig.lua`, is listed in [Appendices C](#) and [D](#). In [Appendix E](#), I present the results of an examination, which is of course not meant to be statistically representative, of the actual counts of ligature suppression instances performed by `selnolig` in two fairly short novels by Jack London (*Call of the Wild* and *The Sea Wolf*) and one longer German novel, *Die Buddenbrooks* by Thomas Mann. Unsurprisingly, `selnolig` catches more than 440 instances of morpheme-spanning ligatures in the German novel, and only four instances *combined* across the two English novels. [Appendix F](#) provides a suggested template for reporting bugs and other issues with the package.

2 I’m in a hurry! How do I start using this package?

2.1 How do I load the `selnolig` package?

- If your document is in English and you want to enable a “basic” set of rules to suppress f-ligatures selectively, load the package by issuing the following instruction in the preamble of your document:

```
\usepackage[english]{selnolig}
```

Synonymous options are `UKenglish`, `british`, `USenglish`, `american`, `canadian`, `australian`, and `newzealand`.

If you want to load a set of f-ligature suppression rules that’s broader than the set that’s enabled by default, be sure to also specify the option `broadf`; see [Section 5.2](#). If “historic” and/or “discretionary” ligatures (e.g., *ct*, *st*, *sp*, *th*, *as*, *is*, and *us*) are enabled for your text font(s), be sure to specify the option `hdlig`. The options `broadf` and `hdlig` may be specified independently.

- If your document is written in German, load the package as follows:

```
\usepackage[ngerman]{selnolig}
```

Synonymous language options are `german`, `austrian`, `naustrian`, `swissgerman`, and `swiss`.

- If you load the package *without* an explicit language option, i.e., as

```
\usepackage{selnolig}
```

but if one or more of the language options noted above are specified as options in the `\documentclass` instruction, L^ATeX will pass these options on to the `selnolig` package.

- If no language options are set either when the package is loaded or as options in the `\documentclass` instruction, you will need to provide your own ligature suppression rules. This approach is called for if you write in a language other than German or English—the only two languages currently supported by the `selnolig` package—and are able to devise your own ligature suppression rules using `selnolig`'s `\nolig` and `\keeplig` macros.

2.2 Any hints on how to get started with Lua^ATeX?

The ligature suppression macros of the `selnolig` package *require* the use of Lua^ATeX; they will not work under either pdf^ATeX or X^ATeX. If the `selnolig` package is not run under Lua^ATeX, a warning message will be issued and only the package's supplemental hyphenation rules will be available to the user.

If you've been using pdf^ATeX until now, the requirement to use Lua^ATeX will likely force you to make some changes to your existing documents. Fortunately, these changes should be minor and straightforward to implement because Lua^ATeX is, for the most part, a strict superset of pdf^ATeX. Almost all documents that compile correctly under pdf^ATeX should also compile correctly under Lua^ATeX. The two most important changes you'll need to make are:

- (i) Do not load either the `inputenc` or the `fontenc` package.
- (ii) Be sure to load the `fontspec` package,⁵ and use `\setmainfont`, `\setsansfont`, and related commands to load the fonts you wish to use.

Depending on your T^EX distribution, the default font family used by Lua^ATeX will be either Computer Modern or Latin Modern. (This is true of pdf^ATeX as well, of course.) If you wish to use a different font family, issuing some font-related instructions will be required. *How* to specify fonts and font families and set up various font-related options in Lua^ATeX are topics that go far beyond the scope of this user guide. I urge you to become familiar with the very well-written [user guide](#) of the `fontspec` package.

You will also need to use a T^EX distribution that features a fairly recent version of Lua^ATeX. T^EXLive 2013, T^EXLive 2012, and MiK^ETeX 2.9 satisfy this requirement; versions of T^EXLive before 2011 probably do not. (You really shouldn't be using a by now grossly obsolete version of Lua^ATeX anyway, right?!)

If you use a command-line interface to compile a document named, say, `myfile.tex`, type

```
lualatex myfile
```

rather than either `latex myfile` or `pdflatex myfile` to initiate compilation. If you use a text editing program with pull-down menus or buttons to invoke a suitable compiler, be sure to select Lua^ATeX.

The very first time one runs Lua^ATeX on a document with a new set of fonts, the compilation speed will likely be quite slow because Lua^ATeX (actually, a package loaded by Lua^ATeX) has to create various cache files to store font-related information. Subsequent compilation runs should be much faster.

The answers to the questions entitled [Frequently loaded packages: Differences between pdf^ATeX and Lua^ATeX?](#) and [Using Lua^ATeX as a replacement for pdf^ATeX](#), both posted to [tex.stackexchange.com](#), provide

⁵ If the `selnolig` package is run under Lua^ATeX but the `fontspec` package isn't loaded by the time the `\begin{document}` statement is encountered, `selnolig` will terminate with an error message.

lots of very useful information for people who are new to Lua^AT_EX and are at least somewhat familiar with pdf^AT_EX. Another great resource for people who wish to become more familiar with Lua^AT_EX is [A Guide to Lua^AT_EX](#) by Manuel Pégourié-Gonnard.

2.3 Anything else I need to do or know?

For multilingual support, Lua^AT_EX and the `selnolig` package work well with the `babel` package. If you use the `babel` package, be sure to load `selnolig` *after* `babel`; that way, the supplemental hyphenation patterns provided by the `selnolig` package won't get clobbered by `babel`'s hyphenation settings.⁶

Lua^AT_EX natively supports the so-called UTF-8 input encoding scheme. In fact, UTF-8 is also the *only* input encoding scheme that Lua^AT_EX knows about. Nowadays, many modern T_EX-aware editors support UTF-8 directly; `selnolig` should have no problems with T_EX files produced by these editors. Older files, however, may use other input encoding systems. If your input files currently use a different input encoding scheme, e.g., `LATIN1`, they need to be converted to UTF-8. Several methods exist for changing a file's input encoding scheme. Please see the posting [How to change a .tex file's input encoding system \(preferably to UTF-8\)?](#) on [tex.stackexchange.com](#) for several possible conversion methods.

If your document is written in German, it is assumed that all vowels with diereses (Umlaute) are entered as `ä`, `ö`, `ü`, etc. rather than, say, as `\"{a}`, `\"{o}`, and `\"{u}` or, if you tend to use the `babel` “shortcuts”, as `"a`, `"o`, and `"u`. Likewise, it's assumed that you enter the “eszett” (“scharfes s”) character as `ß` rather than as `\ss`.⁷ It is also assumed that you use the triple-f (modern) spelling of words such as `Schiffahrt`, `Stofffarbe`, and `griffest` and the double-t (modern) spelling of words such as `Mannschafttest`.

Finally, all `babel`-style “|” ligature-suppressing shortcuts should either be removed entirely or be replaced with `\breaklig` instructions; the `selnolig` package's `\breaklig` macro is explained in [Section 4.1.4](#).⁸

3 The `selnolig` package's approach to breaking up ligatures

3.1 Free, derivational, and inflectional morphemes, and their relationship to ligature suppression

Good typography supports and enhances the readability of the typeset text. There are obviously a great many facets to how typography may contribute to good readability. One aspect is the ease with which readers can discern the *meaning* of the typeset text and its constituent parts—words. Because a typographic ligature groups two or more characters into a composite glyph, it is natural for the reader to “read” a ligature as forming a single unit and, moreover, to associate the ligature with some part of the word's meaning. Whereas this mental association of visual unity and meaning can be helpful when it comes to discerning the meaning of single-morpheme words,⁹ it *may* detract from the word's readability if the word is composite and the

⁶The `selnolig` package is also compatible with the `hyphsubst` package (which, if used, should be loaded with a `\RequirePackage` statement *before* the `\documentclass` instruction). Since mid-2013, one can also use the `polyglossia` package with Lua^AT_EX.

⁷T_EXnically speaking, `selnolig` requires the use of `ä`, `ö`, `ü`, and `ß` only in the search strings of the ligature suppression rules.

⁸On my Lua^AT_EX system, whenever a “|” command is encountered, I either get a bad crash that requires a reboot of the computer (under MacT_EX 2012) or I get a stern error message about “Forbidden control sequence found while scanning use of `\FancyVerbGetVerb`” (under MacT_EX 2013).

⁹Some examples of single-morpheme words containing a ligature are `off`, `fit`, `flat`, `office`, `baffle`, `left`, `act`, `cost`, and `$pin`.

ligature happens to span a morpheme boundary. Ligatures that span a morpheme boundaries *may* impair the word's readability if readers experience the need to do a "double take" to separate out the morphemes used in the composite word.

What exactly are morphemes? Briefly put, morphemes are the smallest linguistic units in a word that carry *meaning*. Because words are, by definition, standalone units of text, each word contains at least one morpheme.¹⁰ Morphemes are classified as *free* if they can stand alone as words (e.g., cat, dog, sea, see), and as *bound* if they can not. E.g., the letter *s* in the words cats, dogs, and rivers indicates the plural forms of the associated nouns; because the *s* particle cannot stand by itself as a word, it is a bound morpheme.

Bound morphemes can be divided further into derivational and inflectional morphemes. A *derivational* morpheme changes the meaning of the associated free morpheme in a fundamental way. E.g., the "un" in "untrue" reverses the meaning of the associated free morpheme "true", and the "ful" in "shelfful" indicates a quantity measure ("two shelffuls of books on typography"). An *inflectional* morpheme signifies a less fundamental change in meaning. In nouns (and, depending on the language, adjectives as well), inflectional morphemes can indicate plural forms (child vs. children, cat vs. cats) and other forms of declination.¹¹ In verbs, inflectional morphemes indicate conjugation, such as a change in tense or of the subject performing the action implied by the verb. E.g., call vs. called, walk vs. walked, and also "swim" vs. "swims", etc.

Words containing more than one morpheme can contain either "just" free morphemes—rooftop, newspaper, etc.—or free and bound morphemes joined together—untrue, shelfful, childish, etc. Bound morphemes in a word generally occur as prefixes or suffixes to the word's "main part" or "stem" (the free morpheme). Prefixes almost invariably represent derivational morphemes (e.g., untrue, review, perform). Suffixes, in contrast, can represent either derivational *or* inflectional morphemes. For instance, the suffixes *like* and *less* in dwarflike and leafless are derivational morphemes, whereas the suffix *ed* in hounded and laughed is an inflectional morpheme.

It is important to realize that not all ligatures that span morpheme boundaries are equally inimical to good readability. Consider, say, the word *umbrellas*, which contains the ligature *as*. Note that this ligature crosses the morpheme boundary between the free morpheme *umbrella* and the suffix *s*. Nevertheless, I'm quite confident that few will claim that the presence of the *as* ligature detracts from the readability of the word *umbrellas*. I believe there are two reasons why this particular word's readability is not impaired by the presence of a ligature that spans a morpheme boundary. First, the suffix *s* is an inflectional morpheme: it "merely" serves to change the noun's state from singular to plural; clearly, most of the composite word's meaning is conveyed by the free morpheme *umbrella*. Second, the ligature occurs at the very *end* of the word rather than, say, closer to the beginning or middle of the word.

The selnolig package adopts the following broad principles: First, ligatures that cross the boundaries of two free morphemes are always suppressed. Second, ligatures that cross the boundary between a free morpheme and a derivational morpheme are also suppressed—with certain exceptions that are explained below. Third, ligatures that span the boundary between a free morpheme and an inflectional morpheme are

¹⁰Please don't try to get me involved in a discussion of what it may mean to have words without meaning...

¹¹In modern English, the virtually sole type of declination is to indicate plural status. In other languages, declination can also occur to indicate genitive, dative, accusative, etc. forms of nouns *and* adjectives. E.g., in German one says das schöne Kind, des schönen Kindes, dem schönen Kinde, etc. The particles *en/es* and *en/e* represent inflectional morphemes associated with the genitive and dative forms of the nouns and adjectives.

not suppressed. In [Section 3.3](#) below, the third principle is shown to be particularly relevant for decisions related to the (non)suppression of certain `ft` and `ff` ligatures in German texts.

Observe that morphemes need not coincide with *syllables*. Indeed, words can contain several syllables but consist of only one morpheme (e.g., apple, orange, banana), or they can contain only one syllable but consist of two or more morphemes. E.g., “cats” and “dogs” each contain two morphemes, and “twelfths” contains three morphemes: the free morpheme `twelve`, the derivational morpheme `th`, and the inflectional morpheme `s`. The fact that a ligature might span a syllable boundary does *not* imply, by the principles set out here, that the ligature should be suppressed.

Consider, for instance, the German words `Affe`, `Griffel`, `Kaffee`, `Koffer`, `Löffel`, `Muffel`, and `Schiffe`: All feature a syllable boundary between the `fs`, yet the `ff` ligature needn’t be broken up because the `ff` character pair doesn’t span a morpheme boundary in any of these words. Should TeX need to hyphenate one of these words to generate a well-typeset paragraph, it can of course do so—and break up the `ff`-ligature in the process. There’s no need, though, to break up any of these `ff`-ligatures pre-emptively just because the words *might* get hyphenated. In contrast, observe that because the `ft` character pair in “fifth” spans a morpheme boundary, the `ft` ligature is suppressed—even though no syllable boundary is present (since it’s a one-syllable word).

TeXnically speaking, the `selnolig` package performs its job of suppressing ligatures selectively by inserting special “whatsit entities” into the input stream. These whatsits serve to prevent character pairs (or triples) from being replaced by single-glyph ligatures. The whatsits items do not come into play during other parts of LuaTeX’s paragraph-building algorithm, say, the hyphenation algorithm.

3.2 `selnolig`’s ligature suppression rules: English language case

Typographic ligatures are suppressed if the following conditions apply to a word:

- if two free morphemes are joined: `halfline` → `halfline`, `halfife` → `halfife`, `cufflink` → `cufflink`, `halftone` → `halftone`, `pastime` → `pastime`, `houndstooth` → `houndstooth`, `Charlestown` → `Charlestown`, `painstaking` → `painstaking`, `arctangent` → `arctangent`, `passport` → `passport`, `newspaper` → `newspaper`, `Hyannisport` → `Hyannisport`, `clothespin` → `clothespin`, `seastrand` → `seastrand`, `Catskills` → `Catskills`, `Peekskill` → `Peekskill`,¹² etc.

- if a prefix and main word are joined: `offload` → `offload`, `mistake` → `mistake`, `mistrust` → `mistrust`, `displease` → `displease`, `suspend` → `suspend`, `asea` → `asea`, `ultrasound` → `ultrasound`, etc.

Note: If the main word, etymologically speaking, starts with `sp` or `st`, the `sp` and `st` ligatures *are* used even if the prefix ends in `s`: `disperse`, `dispirit`, `distant`, `distill`, `distress`, etc.

- if a main word is followed by a free-morpheme suffix beginning with `f` or `l`: `shelfful` → `shelfful`, `leafless` → `leafless`, `dwarflike` → `dwarflike`, `leaflet` → `leaflet`, `soulless` → `soulless`, etc.

Note that the suffixes used above—`ful`[1], `less`, `let`, and `like`—are all free morphemes. In contrast, `ly`, if used to make adjectives into adverbs, is a derivational morpheme. The `fl` ligature is thus *not* broken up for words such as `briefly` and `chiefly` (unless the `broadf` option is set).

¹²The relevant morpheme in the last two words in this list is `kill` (from an old Dutch word for stream), not `skill`.

- If the main word ends with an `f` and the suffix starts with an `i`, the `fi` and `ffi` ligatures are *not suppressed* (unless, again, the `broadf` option is set). Examples: `elfin`, `selfish`, `fluffily`.
- The `ft` ligature is also suppressed for words that end in `fth` or `fths`: `fifth` → `fifth`, `twelfths` → `twelfths`. Note that the particle `th` contained in these words is a derivational morpheme.

If the `broadf` package option is set, the `selnolig` package will also suppress

- `fi` and `ffi` ligatures if the main word ends in `f` and the suffix starts with an `i`: `elfin`, `selfish`, `golfing`, `surfing`, `beefier`, `fluffily`, `fluffiness`, `goofiness`, `standoffish`, `jiffies`, `buffiest`, etc.;
- `fl` and `ffl` ligatures in adverbs ending in `f1y` and `ff1y`, such as `chiefly`, `briefly`, and `gruffly`; and
- `ft` ligatures in words such as `fifty` and `fiftieth`.

The option `broadf` is *not* enabled by default. This is because I believe that any gains in readability that might result from breaking up the `f`-ligatures caught by the `broadf` rules are likely to be minor and aren't worth running the serious risk of creating unsightly visual clashes caused by unligated `fi`, `ffi`, `fl`, and `ffl` glyphs.

If the package's `hdlig` option is set, an additional ligature-suppressing principle is activated:

- The `st` and `sp` ligatures are also suppressed for words with Greek roots that contain the character triples `sth` and `sph`; examples: `isthmus` and `atmosphere`. Typesetting these words as `isthmus` and `atmosphere`, i.e., with the very distinctive looking `st` and `sp` ligatures, risks reducing their readability, because doing so would obscure the presence of the `th` and `ph` character pairs which derive from single Greek letters θ/ϑ and ϕ/φ , respectively. For these words, then, it seems advisable to suppress the `st` and `sp` ligatures even though, strictly speaking, no morpheme-crossing issues are involved.

In addition, as is explained in more detail in [Section 5.5](#), the ligatures `fb`, `fh`, `fj`, and `fk` are suppressed *globally* for English language documents. This is done because there seem to be no words of *English* origin for which these ligatures do not span a morpheme boundary. However, these ligatures are not suppressed for certain words of non-English origin, such as `Kafka`, `fjord`, and `fell`.

3.3 Ligature suppression rules: German language case

For German words, the following rules apply when it comes to deciding which ligatures to break up and which ones to permit. These rules are built mainly from statements found in the *Duden* and various websites that have taken an interest in this subject—with adaptations for the `ft` and `fft` ligatures.

- Case 1: Joining of two free morphemes: Ligatures are suppressed. Examples: `Schilfinsel` → `Schilfin-sel`, `Baustoffingenieur` → `Baustoffingenieur`, `Wasserstoffionen` → `Wasserstoffionen`; `Impffurcht` → `Impffurcht`, `Senffabrik` → `Senffabrik`, `Ablauflogik` → `Ablauflogik`, `Schorfflecken` → `Schorfflecken`; `Zwölffingerdarm` → `Zwölffingerdarm`; `Brieftaube` → `Brieftaube`, `elfteilig` → `elfteilig`, etc.
- Case 2: Joining of a prefix (whether a free or a derivational morpheme) ending in `f` and a main word (free morpheme) starting with `b`, `f`, `h`, `i`, `j`, `k`, `l`, or `t`: Ligatures are suppressed. By far the most

common prefix that gives rise to the need to suppress various f-ligatures at the junction of a prefix and main word is the word “auf”, as in aufbrechen, auffassen, Aufführung, aufliegen, auffischen, aufhören, aufisst, aufjaulen, aufklingen, Auflage, Auftrag, auftreten, etc.

- Case 3: Joining of a main word (free morpheme) ending in “f” or “ff” and a suffix (either a derivational or an inflectional morpheme) starting with “f”, “i”, “l”, or “t”.
 - Case 3a: Suffixes (bound morphemes) that start with an “f”, e.g., -fach and -faltig: The ff-ligature is suppressed. Examples: fünffach and zwölffaltig.
 - Case 3b: Suffixes (bound morphemes) that start with an “i”, e.g., -ig, -in, and -isch: The fi and ffi ligatures are *not* suppressed. Examples: streifig, äffisch, Chefin, Chefinnen.
I haven’t found a clear justification for this rule so far. I assume the rule is there because unligated fi and ffi character pairs are potentially sufficiently unsightly to make them stand out as an infraction against good typography that’s even more grievous than having fi and ffi ligatures that span the boundary between a main word and a suffix.
 - Case 3c: Suffixes that start with an “l”, e.g., -lich, -ling, -lein and -los: The fl-ligature is suppressed. Example words: trefflich, höflich, Prüfling, Köpflin, and straflos.
 - Interlude I: In ambiguous cases that could give rise to fl-ligatures that involve certain suffixes, according to *Duden* preference should be given to “how the syllables are pronounced and how a word would be hyphenated”. For instance, *Duden* says that the fl-ligature should be suppressed in the words Verzweiflung, Bezweifler, schweflig, and würflig.¹³
This convention may also be applied to justify the non-use of the fl-ligature in words such as knifflig and mufflig as well as in the present-tense/first-person-singular forms of the verbs büffeln, löffeln, schaufeln, stiefeln, verteuflern, and zweifeln: these form are typeset *without* the fl/ff-ligature, i.e., as büffle, löffle, schaufle, stiefler, verteufler, and zweifle, respectively.
 - Interlude II: If a word *ends* with an fl character pair because an abbreviation is in effect, *Duden* says it’s OK to use the fl-ligature even if the f and l characters belong to different morphemes. E.g., in the abbreviation “Aufl.,” the fl-ligature *is* employed even though the ligature should not be used for the full, unabbreviated form of the word (*viz.*, Auflage).

¹³Note that the real suffixes in these words are ung, er, and ig—not lung, ler, and lig. Suppressing the fl-ligature for these words is thus not a simple matter of not letting a ligature span the “gap” between a main word and suffix. In my opinion, the rationale generally given for suppressing the fl-ligature in these cases—reliance on how the syllables are divided and how the composite words are hyphenated—is not entirely satisfactory. This is because, morphologically speaking, the main words Schwefel, Würfel, and Zweifel each contain two morphemes: a stem and the *derivational* morpheme e1: Schwef|e1, Würf|e1, and Zweifel|e1. It is therefore not necessary, in my opinion, to create a new rule to justify the (non-)use of the fl-ligature for these cases. Given the presence of two morphemes in each of the main words, one could simply rely on the general rule of not letting ligatures span morpheme boundaries within the main words to motivate the suppression of the fl-ligature for words such as schweflig, würfle, and Verzweiflung, as their morphological components are schwef|[e]1|ig, würf|[e]1|e, and Ver|zweif|[e]1|ung.

It’s fair to say, though, that most modern German speakers are only vaguely cognizant of the fact that the e1 particle constitutes a morpheme in words such as Würfel and Griffel—and that they are probably entirely unaware of this fact for words such as Schwefel and Zweifel. To be sure, the typographical convention adduced by *Duden* for suppressing the fl-ligature in words such as schweflig, Verzweiflung, and würfle does *not* appear to be based on the fact that letters f and l in these words belong to different morphemes.

Although not mentioned explicitly by *Duden*, I believe the convention mentioned in the preceding paragraph may be extended to justify the use of the ff-ligature in the abbreviated word “Auff.” (full form: Aufführung—no ff ligature) and of the ft-ligature in “Auft.” (full form: Auftrag—no ft ligature).

This convention further suggests (implies?) that it’s permissible (a) to use the ff ligature in surnames that end in ff, such as Orff and Hausdorff, and (b) to use the ffi- and ffi-ligatures in abbreviated names such as Steffi and Steffl.

- Case 3d: Suffixes (derivational or inflectional morphemes) starting with t. Unfortunately, not much official wisdom seems to exist to guide this case, possibly because the ft and ffi ligatures are not (yet?) used as widely as are the other f-ligatures. The following four rules, and especially the second one, should therefore be understood to be somewhat provisional.

- * The convention mentioned in “Interlude II” above, about not breaking up an fl-ligature if it occurs at the very end of a word (as in “Aufl.”), may be extended to apply to the case of ft and ffi ligatures as well, i.e., they are not suppressed *if* they occur at the very ends of words (or word fragments that have separate meaning), as in verschärft, gestreift, gerafft, Dahingerafftsein, unbedarft, and Unbedarftheit.

Note that the ft and ffi ligatures span a morpheme boundary in these cases: the single-letter second morpheme, the letter t, is an *inflectional* morpheme that indicates a form of conjugation of the associated verb (viz., past tense and/or past participle).

- * Should ft and ffi ligatures be broken up in past tense and past-participle forms of verbs that do not end in ft but, instead, in -fte, -ften, -ftes, -ftest, etc? Example words: streifte, rafften, and schlürftest. Because these suffixes are “merely” *inflectional* rather than derivational morphemes, the selnolig package does *not* break up the ft and ffi ligatures in these cases either. Thus, the words will be typeset as streifte, schlürftest, and rafften rather than as streifte, schlürftest, and rafften.¹⁴
- * Again appealing to the convention mentioned in “Interlude II”, it would also seem OK to use the ft-ligature in expressions such as “zu fünft” and “die zwölftschnellste Sprinterin Bayerns”: Even though the t character is a *derivational* morpheme in these words, the ligature occurs at the very end of the word or word fragment. In the case of the word “zwölftschnellste”, the argument for keeping the ft ligature may also be based in part on the observation that the entire fragment “zwölft” is a prefix to “schnellste”; grouping the t character visually to its stem, zwölf, via an ft-ligature surely enhances the overall readability of the sixteen-character word zwölftschnellste, right?
- * In contrast, the ft-ligature should *not* be used in “Beethoven’s Fünfte Sinfonie” and “zum elften Mal”. The argument for breaking up the ft-ligature in the words “Fünfte” and “elften” rests on the fact that the particles te and ten are derivational morphemes, rather than on the fact that the syllable boundaries in these words happen to fall between the letters f and t.

¹⁴I haven’t yet come across any kind of authoritative discussion of this specific case. Should someone be able to furnish a good counterargument to the setting proposed here, I would be happy to change the settings accordingly.

- Case 4: A free morpheme *ends* in *ft* (e.g., Saft, Kraft, Luft, Duft, Haft, and Vernunft) and is joined either to another free morpheme or to a suffix that’s a bound morpheme. Example words: Saftladen, Säfte, Kraftfahrzeug, Luftagentur, duftend, bekräftigen, Haftung, and vernünftig. Because the *ft* character pair doesn’t cross a morpheme boundary, the *selnolig* package does *not* break up the *ft* ligature. Thus, the words are typeset as Saftladen, Säfte, Kraftfahrzeug, Luftagentur, duftend, bekräftigen, Haftung, and vernünftig. The fact that a *syllable boundary* occurs between the letters *f* and *t* in some of these words should not affect the decision whether or not to employ the *ft* (or *fft*) ligature.

In addition, as is explained in more detail in [Section 5.5](#), the ligatures *fb*, *fh*, *fj*, and *fk* are suppressed *globally* for German language documents. This is done because there seem to be no words of *German* origin for which these ligatures do not span a morpheme boundary. However, these ligatures are not suppressed for words of non-German origin, such as Kafka, Sognefjord, and Dovrefjell.

4 Structure of the *selnolig* package

4.1 The main user commands

The four main user macros of the *selnolig* package are `\nolig`, `\keeplig`, `\uselig`, and `\breaklig`. The first two macros are meant to be used in the preamble to set up ligature-suppression rules on a document-wide basis. The latter two may be used, as needed, within the body of the document on an *ad hoc* or case-by-case basis to either supplement or override the rules set up by the `\nolig` and `\keeplig` instructions.

4.1.1 The `\nolig` macro

The package’s main user macro is called `\nolig`. Each `\nolig` instruction, or rule, takes two arguments: a search string, and a string containing a “|” character that indicates where in the search string the non-ligation “whatsit” should be inserted. E.g., the rule

```
\nolig{lfful}{lf|ful}
```

serves to suppress the *ff*-ligature in words such as “shelfful”, “bookshelfful”, and “selffulfilling”.

It is possible to indicate more than one ligature suppression point in the second argument of a `\nolig` rule. For instance, one *could* specify the rule `\nolig{Auflaufform}{Auf|lauf|form}` to suppress both the *fl*- and the *ff*-ligature in the word *Auflaufform* and its plural form, *Auflaufformen*. For added flexibility, though, the *selnolig* package actually uses two separate `\nolig` rules to suppress the two ligatures in this word; see also [Section 6.3](#).

It is possible to use Lua-style wildcard characters in the search string, as long as these characters occur *after* the non-ligation point. For example, the file *selnolig-german-patterns.sty* sets up the rules

```
\nolig{Dorff[aäeiloöruü]}{Dorf|f}
\nolig{dorff[aäeiloöruü]}{dorf|f}
```

to search for words that contain the strings `Dorff` and `dorff` followed by a letter in the set `äëïloöruü`.¹⁵ Incidentally, it is not absolutely necessary, in the second argument of the `\nolig` command, to provide any material *after* the vertical bar that indicates the non-ligation point. However, the readability of your `\nolig` rules may suffer if you suppress that material.

If you examine the `\nolig` rules provided in the files `selnolig-german-patterns.sty` and `selnolig-english-patterns.sty`, you’ll notice soon that some redundancy is built in. For instance, the need to suppress the `ff`-ligature in “auffallen” happens to be met by both `\nolig{auff}{auf|f}` and `\nolig{ffall}{f|fall}`. This redundancy is deliberate, because not all words that might fit one pattern will also fit the other. Providing some redundancy of this type seems like a reasonable way to proceed.

As with all L^AT_EX instructions, the arguments of `\nolig`, `\keeplig`, and `\uselig` commands are case-sensitive.

4.1.2 The `\keeplig` macro

The macro `\keeplig{<string>}` allows users to create rules that override `\nolig` rules selectively: for words that contain fragment `<string>`, the corresponding `\nolig` rule will not be executed. For a `\keeplig` rule to work properly, then, the command’s argument must be a string that includes *as a subset* a string treated by one or more `\nolig` rules.

The `\keeplig` macro is very useful tool because it permits devising a (much) smaller set of broader, i.e., less restrictive, `\nolig` rules; any Type-II errors that may arise from having `\nolig` rules whose scope is too broad can be undone by providing judiciously crafted `\keeplig` rules.¹⁶

Consider the following example: If the `ngerman` language option is set, the `selnolig` package uses the rule

```
\nolig{flich}{f|lich}
```

to break up the `fl`-ligature in a multitude of words that end in the suffix `lich` (a derivational morpheme): `begrifflich`, `beruflich`, `brieflich`, `glimpflich`, `hilflich`, `höflich`, `käuflich`, `sträflich`, `tariflich`, `trefflich`, `unerschöpflich`, and `verwerflich`, to name but just a few. This `\nolig` rule, incidentally, also (correctly) catches the word “`Lauflicht`”, which contains the free morphemes `Lauf` and `licht`,

However, the scope of this `\nolig` rule is a bit too broad (or, if you will, it is insufficiently restrictive) because it also catches words such as `Pflicht` and `verpflichten` for which the `fl`-ligature should *not* be suppressed. Rather than provide a large number of more restrictive `\nolig` rules aimed at avoiding catching the `Pflicht`- and `pflicht`-words, the package provides the command

```
\keeplig{pflicht}
```

This rule tells `selnolig` to override the action of the `\nolig{flich}{f|lich}` rule for all words that contain the string `pflicht`. Most words affected by this `\keeplig` rule happen to contain the strings “`Pflicht`” and “`pflicht`”. In addition, this rule also helps preserve the `fl`-ligature in words such as “`flichst`” and “`verpflicht`” (the second- and third-person-singular forms of the verbs `flechten` and `verflechten`).

¹⁵In case you’re curious: These particular search strings are used so as not to suppress the `ff`-ligatures in words that *end* in either `Dorff` or `dorff`, as would be the case with the surnames `Dorff` and `Hausdorff`.

¹⁶In the present context, a Type-II error is the suppression of a ligature that is, in fact, valid for the word at hand.

It’s important to keep the following in mind: It is *not necessarily* the case that ligatures contained in the argument of a `\keeplig` rule will in fact be used in words that contain the rule’s search string. Why?! It is because, as was noted above, *more than one* `\nolig` rule can apply to a given word. Consider, for instance, the word `Lauflicht` that was mentioned earlier. This word happens to be caught by two `\nolig` rules and one `\keeplig` rule provided in the file `selnolig-german-patterns.sty`:

```
\nolig{auf1}{auf|1}
\nolig{flich}{f|lich}
\keeplig{flicht}
```

For the word `Lauflicht`, `\keeplig{flicht}` serves to undo the action of `\nolig{flich}{f|lich}`. However, because the string `auf1` is *not* a subset of the string `flicht`, `\keeplig{flicht}` does not undo the action of `\nolig{auf1}{auf|1}`. Hence, the word `Lauflicht` ends up being typeset—correctly!—as `Lauflicht`, i.e., *without* the `fl`-ligature.

Interestingly, the rule `\keeplig{flicht}` is itself a bit too broad because it improperly catches the composite noun `Sumpflicht`, for which the `fl`-ligature *should* in fact be suppressed. To address this case, the file `selnolig-german-patterns.sty` provides the rule `\nolig{Sumpfl}{Sumpf|1}`; for the word `Sumpflicht`, this `\nolig` rule is not overridden by the rule `\keeplig{flicht}`. This `\nolig` rule also serves to suppress the `fl` ligature in words such as `Sumpflabkraut` and `Sumpfleiche`.

4.1.3 The `\uselig` macro

The `selnolig` package also provides the user command `\uselig`, which acts very much like the `\keeplig` command to override the action of a `\nolig` rule. However, it does so purely on a one-off basis. E.g., the command `\uselig{fj}` will typeset “`fj`” even if the rule `\nolig{fj}{f|j}`—which suppresses the `fj` ligature on a global, i.e., document-wide basis—is active; *without* `\uselig`, you’d get “`fj`”.

You should use `\uselig` instructions only for single words and word fragments; don’t use them for longer stretches of text. If you need to suspend the operation of the ligature suppression macros for longer stretches, including entire paragraphs or more, you should use the macros `\selnoligoff` and `\selnoligon`, which are described in more detail in [Section 6.4](#).

4.1.4 The `\breaklig` macro

The macro `\breaklig`, which doesn’t take an argument, is provided as a hopefully easy-to-remember substitute for the lower-level L^AT_EX command “`\- \hspace{0pt}`”. You should insert this macro in places where you want to break up a ligature on an ad-hoc basis and also wish to permit hyphenation. To suppress a ligature on an ad-hoc basis *without* introducing a potential hyphenation point, insert the instruction “`\kern0pt`”.

For instance, to suppress the *sk* ligature in the word `groundskeeper` on a one-off basis, one might enter it as “`grounds\breaklig keeper`” in order to obtain *groundskeeper* rather than *groundskeeper*. To suppress the *sk* ligature for this word as well as for words such as *greenskeeper* and *miskeep* throughout the entire document, one could issue the directive `\nolig{skeep}{s|keep}`; the package provides just such a rule.

4.2 Components of the selnolig package

The selnolig package has the following components:

- The main “driver” file is called `selnolig.sty`. It sets up the package’s main user macros, `\nolig`, `\keeplig`, `\uselig`, and `\breaklig`, that were explained in detail in the preceding subsection and loads several other files.
- The package’s lua code is in the file `selnolig.lua`.
- The ligature suppression rules for English and German language documents are contained in the files `selnolig-english-patterns.sty` and `selnolig-german-patterns.sty`, respectively.
- Supplemental hyphenation exception patterns, mostly for composite words that involve ligatures that are suppressed by the package’s `\nolig` rules, are contained in the files `selnolig-english-hyphex.sty` and `selnolig-german-hyphex.sty`.
- The user guide—the document you’re reading right now—is provided in the file `selnolig.pdf`; the associated source code is in the file `selnolig.tex`.
- Ancillary files: the files `selnolig-english-test.tex` and `selnolig-german-test.tex` load the selnolig package as well as either `selnolig-english-wordlist.tex` or `selnolig-german-wordlist.tex`. They serve to demonstrate the output of the selnolig package when run on lists of English or German words that are candidates for non-use of ligatures. The files `selnolig-english-test.pdf` and `selnolig-german-test.pdf` contain the results of compiling the test programs. Assuming your T_EX distribution is either T_EXLive or MiK_TE_X, you can access these files by typing `texdoc selnolig-english-test` or `texdoc selnolig-german-test` at a command prompt.

The “driver” file `selnolig.sty` starts by setting up several Boolean switches to structure the processing of options. It then loads the file `selnolig.lua`, which contains the package’s lua code and sets up the user macros discussed in the preceding subsection.

The remaining steps in the startup process depend on which language-related options were selected:

- If *no* language-specific options are in effect, the setup process terminates. Users may, of course, provide their own `\nolig`, `\keeplig`, `\uselig`, and `\breaklig` instructions.
- If the `english` option (or one of its synonymous options) is set, the files `selnolig-english-patterns.sty` and `selnolig-english-hyphex.sty` are loaded. The former file contains a detailed list of `\nolig` and `\keeplig` rules adapted to English language typographic usage; [Appendix A](#) provides a complete listing of these rules. The latter file contains a list of hyphenation exceptions, mainly for words that contain one or more potential non-ligation points and for which T_EX’s hyphenation algorithm either misses valid hyphenation points or selects invalid hyphenation points; see [Section 6.2](#) below.
- If the `ngerman` option (or one of its synonymous options) is set, the files `selnolig-german-patterns.sty` and `selnolig-german-hyphex.sty` are loaded. The former file contains ligature suppression rules appropriate

for German typographic usage; [Appendix B](#) lists its contents. The latter file provides additional hyphenation rules for German-language words.

- If the user specifies both the `english` and `ngerman` options (or some of their synonymous options), *both* language-specific style files will be loaded. Under normal circumstances, a user will probably want to load only one or the other set of language-specific files, but not both.

The following is an admittedly rough and rather imperfect indication of just how much more complex the task is of creating a set of ligature suppression rules for German than it is for English: As of the mid-May 2013 version of the `selnolig` package, the “basic” set of English language ligature suppression rules for “common” f-ligatures consists of 32 `\nolig` and 17 `\keeplig` directives.¹⁷ In contrast, the set of German language ligature suppression rules for “common” f-ligatures consists of roughly 700 `\nolig` and 335 `\keeplig` directives. A ratio of roughly 1:20 in terms of detail and complexity!

5 Additional ligature-related matters

5.1 The `noftligs` option

By default, the `selnolig` package will load rules to suppress `fi` and `ffi` ligatures selectively, for both English and German documents. In case you want to suppress these two ligatures *globally* rather than selectively, you could specify the option `noftligs` when loading the package. Doing so will make the package set up the simple rule `\nolig{ft}{f|t}` rather than load many separate rules for suppressing `fi` ligatures selectively.¹⁸ You may also wish to specify the `noftligs` option if the font you use in your document doesn’t even feature `fi` and `ffi` ligatures.

5.2 English language case: The `broadf` and `hdlig` options

The ligature suppression patterns for English language words, contained in the file `selnolig-english-patterns.sty` and listed in [Appendix A](#) below, are grouped into four parts. The first two parts concern the suppression of f-ligatures. Part 1 provides a fairly limited, or “basic”, set of patterns that will always be executed, and Part 2 contains a broader set of ligation suppression rules that will be executed if the `broadf` option is specified.

As noted in [Section 3.2](#) above, for English-language documents only the fairly limited number of f-ligature suppression rules contained in Part 1 of the file is enabled by default. This is done because eliminating the morpheme-crossing f-ligatures caught if the `broadf` option is set does not appear to be a major concern in English-language typography. There simply doesn’t appear to be a need to suppress the `fi` (`ffi`) ligature words that end in `f` (`ff`) followed by the particles `-ing`, `-ish`, `-ier`, `-iest`, `-ily`, and `-iness`. Any gain in readability resulting from suppressing these `fi` and `fl` ligatures would appear to be more than offset by unsightly visual clashes created by unligated `fi`, `ffi`, `fl`, and `ffl` combinations.

¹⁷Including the rules that are activated if the `broadf` and `hdlig` options are both activated, the tally rises to about 420 `\nolig` and 52 `\keeplig` instructions.

¹⁸For German language documents in particular, suppressing `fi` and `ffi` ligatures *globally* may help speed up compilation noticeably, as there will be roughly 180 `\nolig` and 60 `\keeplig` instructions fewer to run on the document.

Part 3 of the file `selnolig-english-patterns.sty`, which is enabled if the `hdlig` option is set, provides ligature suppression rules for the `ct`, `st`, and `sp` ligatures. Examples are words such as *arctangent* (not: *arctangent*), *painstaking* (not: *painstaking*), *mistake* (not: *miſtake*), and *trespass* (not *trespass*).

Setting the `hdlig` option also enables ligature suppression rules for additional discretionary ligatures such as *th*, *at*, and *et*. These ligatures might be deemed inappropriate for use in words such as *lighthouse*, *pothole*, *aromatherapy*, *albatross*, *ninety*, and *nonetheless*. With the `hdlig` option set, these words will be typeset as *lighthouse*, *pothole*, *aromatherapy*, *albatross*, *ninety*, and *nonetheless*. Ligature suppression rules are provided for the following discretionary ligatures, which occur only in the *italic* font shape of the font families used in this document: *th*, *at*, *et*, *as*, *is*, *us*, *ll*, *fr*, and *sk*. Part 3 of [Appendix A](#) lists these rules.

Part 4 of the file `selnolig-english-patterns.sty`, which is also processed if the `hdlig` option is set, deals with cases where one discretionary typographic literature, say *as*, might pre-empt the use of a more appropriate but trailing typographic ligature, say *st* or *sp*, in words such as *fast* → *faſt* and *clasp* → *claſp*. Note that the issue being addressed in this part is not that of a ligature improperly spanning a morpheme boundary; instead, it is the possibility that T_EX might pre-empt one typographic ligature with another ligature within one and the same morpheme. This issue is discussed in more detail in [Section 5.6](#) below.

5.3 Composite words with ambiguous morphology

Some composite words can be made up of two different morpheme pairs, or even morpheme triples. For instance, the German words *Saufladen* and *Wachstube* may be constructed as *Sauf-laden*/*Sau-fladen* and as *Wachs-tube*/*Wach-stube*, respectively. In one case, using the `fl` and `st` ligatures would be wrong; in the other, using the ligatures helps indicate the intended meaning of the composite words. For words such as these, software isn't smart enough to “discern” which possible meaning is intended.¹⁹ Writers, of course, could choose to insert explicit hyphen characters to indicate the intended meaning.

The preceding two examples each involve pairs of free morphemes. More complicated cases can occur too. For instance, the composite word *Surftest* can have a meaning that involves a free morpheme and an inflectional morpheme (indicating the past-tense use of the verb), whereas the other meaning involves two free morphemes. Consider the questions “*Surftest* Du vergangene Woche in Hawaii?” and “*Hat die Athletin den Surftest* bestanden?” In the second question, it would clearly be wrong to use the `ft`-ligature; the word *Surftest* is therefore entered as “`Surf\breaklig test`” in that question.

An even more complicated example is the word *Chefinnenleben*, which contains three morphemes. This word can be deconstructed either as *Chefinnen-leben* (“lives of female bosses”) or as *Chef-innenleben* (“inner life, or lives, of a boss”); the word’s middle particle—“*innen*”—can function both as a suffix to “*Chef*” and as a prefix to “*Leben*”. Only in the second case is it wrong to use the `fi`-ligature.

It turns out that the rules of the `selnolig` package are set so as *not* break up the `fi`-ligature in the shorter words *Chefin* and *Chefinnen*, in keeping with the principle that the `fi`-ligature is permitted for suffixes that start with an “*i*”. In contrast, `selnolig` will break up the `fi`-ligature in the longer words *Chefinnenleben* and *Chefinnenräume*; in these cases, the working assumption is that *innen* acts as a prefix to the third

¹⁹If the `ngerman` option is set and the `babel` package is loaded as well, the `selnolig` package will break up the `fl` ligature in *Saufladen* but not the `st` ligature in *Wachstube*, i.e., the words will be typeset as “*Saufladen*” and “*Wachstube*”, respectively. If that’s *not* what you want, you’ll need to mark up the words explicitly as follows: `\use1ig{Saufladen}` and `Wachs\breaklig tube`.

morpheme (Leben or Räume). If this is *not* what you want, i.e., if you really do mean to refer to lives or spaces of female bosses, be sure to use `\uselig{fi}` instructions to preserve the fi-ligatures. Better yet, use explicit hyphens: Chefinnen-Leben and Chefinnen-Räume. And, while you're at it, do consider writing the other forms as Chef-Innenleben and Chef-Innenräume. Your readers will thank you.

Summing up: Some composite words are morphologically ambiguous. For such words, it is (currently) not possible to program software to decide unambiguously whether or not ligatures that might occur in the words should be suppressed. The best advice I can give is to be on the lookout for such words and to take corrective action should `selnolig`'s choices be wrong.

5.4 How to provide additional ligature suppression patterns

As already noted, it's not possible to claim that the non-ligation rules provided in `selnolig-english-patterns.sty` and `selnolig-german-patterns.sty` are complete or, for that matter, will *ever* be complete. If you come across words containing ligatures that ought to be suppressed but aren't caught (yet) by the `selnolig` package, you could do the following. First, you could insert `\breaklig` instructions to suppress the ligatures on a case-by-case basis; conversely, if you discover an instance for which `selnolig` improperly breaks up a ligature, you could override that action by encasing the character pair (or triple) in a `\uselig` statement. Second, you could create your own `\nolig` and `\keeplig` rules to deal with the cases you've discovered on a document-wide basis. A third option, naturally, is to bring this case to the attention of the maintainer of the `selnolig` package and ask him/her to update the package's ligature suppression rules...

To give an extended example of how one might go about augmenting the set of ligature-suppression rules already provided by the `selnolig` package, suppose that you've been tasked with preparing a special edition of Thomas Mann's novel *Der Tod in Venedig*. Suppose further that you have chosen to use an "Antiqua" ("Roman") font—which, naturally, features a ligature for the `ffl` character triple—to typeset this special edition, because fewer and fewer people nowadays can manage to read with ease text set in a `period-appropriate blackletter font`. During your preparations, you happen to notice (i) that the novel contains the word `inbegriffleitend`²⁰ and (ii) that the `selnolig` package does not (yet) provide a rule that suppresses the `ffl`-ligature for this word.

To meet the need to suppress the `ffl`-ligature in `inbegriffleitend`, you could insert a `\breaklig` instruction, i.e., enter it as `"inbegriff\breaklig leitend"`. (Doing so isn't inefficient in the present example because the word `inbegriffleitend` occurs exactly once in the novel.) Alternatively, you could devise a new `\nolig` rule to catch this word. For instance, you could add the following `\nolig` rule (to be inserted in your document's preamble, after the `selnolig` package has been loaded) to suppress the `ffl` ligature in `inbegriffleitend` as well as in the far more common words `Jugendtreffleiter` and `Kunststoffleitung`:

```
\nolig{ffleit}{ff|leit}
```

²⁰This word really does occur in the aforementioned novel! This novel may very well also be the *only place* ever where you'll encounter this word. I performed a Google search for the term "inbegriffleitend"; the only hits, apart from online editions of the novel itself, were the sites of a couple of French bloggers who agonized over how this word might possibly be translated from German to French...

With this rule in place, the words will be typeset as *inbegriffleitend*, *Jugendtreffleiter*, and *Kunststoffleitung*, respectively. Just in case this discussion has made you curious: the file `selnolig-german-patterns.sty` provides the more general (i.e., less restrictive) rule `\nolig{fleit}{f|leit}` to catch these words.

When designing your own `\nolig` and `\keeplig` rules, you would ideally do so in a way that ensures that the rules are neither too specific (and hence only apply to a very small set of words) nor too general (and hence end up applying to words for which the rule wasn't meant to apply).

Of course, this may be easier said than done. Consider, say, what would happen if you came up with the rule

```
\nolig{flei}{f|lei}
```

This rule would certainly succeed in breaking up the *ffl*-ligature in the words *inbegriffleitend*, *Jugendtreffleiter*, and *Kunststoffleitung*. It will also break up the *fl*-ligature in *Laufleistung*, *Häuflein*, *Kreislaufleiden*, *Scherflein*, and many more words. However, this rule would also *incorrectly* break up the *fl*-ligature in many other words, including *fleissig/fleißig*, *fleischig*, *Hackfleisch*, and *Diplomfleißarbeit*; I believe most German readers would prefer to see these words typeset *with* the *fl*-ligature, i.e., as *fleissig/fleißig*, *fleischig*, etc. When in doubt, try to err on the side of making your `\nolig` rules a bit too restrictive.

5.5 How to use the `selnolig` package to suppress certain ligatures *globally*

The main purpose of the `selnolig` package is, obviously, to disable certain ligatures selectively. However, it can also be used to suppress ligation globally for selected character pairs.²¹

For instance, suppose that you are typesetting a Turkish text. The Turkish alphabet features both a dotted *i* and a dotless *ı* character. I understand that in Turkish typesetting practice, the *fi* and *ffi* ligatures should *never* be employed, so as to avoid creating any doubts as to whether it's an *i* or an *ı* character that follows the “f” character. To satisfy the need of Turkish typography for global suppression of the *fi* and *ffi* ligatures, one could place the following instruction in the document's preamble:

```
\nolig{fi}{f|i}
```

Or, suppose that you have a font that provides ligatures for the *fb*, *fh*, *fj*, and *fk* character pairs (as well as, possibly, the *ffb*, *ffh*, *ffj*, and *ffk* character triples). If you wanted to suppress the four former *f*-ligatures globally (and also break up the latter ligatures into *ffb*, *ffh*, *ffj*, and *ffk*, respectively), you could do so by issuing the following commands:

```
\nolig{fb}{f|b}
\nolig{fh}{f|h}
\nolig{fj}{f|j}
\nolig{fk}{f|k}
```

In fact, as was already mentioned in [Section 3](#), these commands are activated automatically if the `ngerman` or `english` language options are set. This is done because I was unable to come up with a single word of

²¹ I first became aware of the potential need for such a feature from reading Frank Mittelbach's posting, [Suppress certain ligatures generally](#), on tex.stackexchange.com.

German or *English* origin involving these character combinations that doesn't also entail a morpheme boundary collision.

Of course, your document may contain words *not* of German or English origin that contain some of these character pairs and do not involve a morpheme boundary crossing. For such words, it is not necessary to suppress the corresponding ligatures. For instance, in the word *Kafka*, one may not wish to suppress the *fk*-ligature for this specific word. The *selnolig* package provides `\keeplig` rules to preserve the *fk*-ligature in names such as *Kafka*, *Safka*, *Piefke*, *Potrafke*, *Sprafke*, *Shirafkan*, *Tirafkan*, and *Rifkin*.²²

Your documents may also feature words of *Nordic* origin that contain the *fj* character pair, such as *Sognefjord* and *Dovre fjell*. Because the *fj* character pair in these words does not span a morpheme boundary, the *fj*-ligature should not be broken up; i.e., the words should be typeset as *Sognefjord* and *Dovre fjell*, respectively. The package therefore provides `\keeplig` rules to take care of (a) words that contain the particles *fjord*, *fjör*, *fjell*, and *fjäll* and (b) names such as *Eefje*, *Sufjan*, *Prokofjew*, and *Astafjew*.

A “rare” typographic ligature that may warrant global suppression, at least for English language documents, is *ij*.²³ To the best of my knowledge, a morpheme boundary crossing occurs for all English language words that contain the *ij* character pair: *antijam*, *bijection*, *demijohns*, and *hijack*. By the logic set forth above, this ligature should therefore be suppressed for all of these words.²⁴ The *ij* ligature also seems inappropriate for most words that came into English from languages such as French, Japanese, and Spanish, including *bijou* (jewel), *gaijin* (foreigner), *jipijapa* (Panama hat), and *marijuana* (Maryjane). (What? Were you maybe thinking of a different meaning of this word? How come?!) The *ij* ligature is therefore suppressed *globally* by the *selnolig* package if the options `english` and `hdlig` are set. However, this ligature *does* get used a lot in Dutch. Thus, the *selnolig* package issues various `\keeplig` directives so that this ligature isn't suppressed for some names and words of Dutch origin, such as *de Bruijn* and *rijsttafel*.²⁵

5.6 What if one ligature pre-empts a trailing, more appropriate ligature?

If a font provides many discretionary ligatures, the likelihood is high that words will occur for which the use of a ligature for the first two characters of a character *triple* might incorrectly pre-empt the use of a more appropriate ligature for the last two characters of that triple. Incidentally, the issue of ligature pre-emption is not limited to “discretionary” ligatures; it can also arise when dealing solely with “common” *f*-ligatures. Suppose, for instance, that a certain font provides *ff*, *fi*, and *fl* ligatures but no *ffi* and *ffl* ligatures. Consider how *TEX* would typeset words containing *ffi* and *ffl* character triples. Left to its own devices, *TEX* would let the leading *ff*-ligature pre-empt the trailing *fi*- and *fl*-ligatures, resulting in typographically incorrect outcomes for words such as *wolffish* (better: *wolffish*), *safflower* (*safflower*), *auffinden* (*auffinden*), and *Schaffleisch* (*Schaffleisch*).

²² Aside: It was Felix Lehmann's desire to preserve the *fk* ligature in the name “Kafka” that stimulated the creation of the package's `\keeplig` macro. Of course, once the `\keeplig` macro was created, I quickly discovered all kinds of further uses for it.

²³ For many fonts I'm familiar with, including the one used for this user guide, the *ij* character pair is available in the upright font shape as a *digraph* rather than as a true, i.e., joined-up, ligature.

²⁴ If this ligature weren't suppressed, the preceding words would be typeset as *antijam*, *bijection*, *demijohns*, and *hijack*.

²⁵ The word *rijsttafel*, incidentally, features three consecutive “rare” ligatures. Another word that contains three rare ligatures, though not consecutive ones, is *isthmus*.

In this section, we examine the use of `\no1ig` rules to address the ligature pre-emption issue, focusing on cases of *st*, *sp*, *th*, and *tz* character pairs being preceded by character pairs (for which the font provides ligatures) that end in *s* or *t*, respectively. This focus is dictated largely by the discretionary ligatures provided by the main text font used for this user guide (Garamond Premier Pro). Other ligature-rich fonts may provide further possibilities for one ligature inappropriately pre-empting that for a trailing character pair.²⁶

Ligatures for *as*, *es*, *is*, and *us* that pre-empt an *st* ligature

Suppose that the text font in use provides ligatures for the *as*, *is*, and *us* character pairs as well as for the *st* character pair. By T_EX's rules for forming typographic ligatures, words that contain the character *triples* *ast*, *ist*, or *ust* will see the first two characters ligated, pre-empting the use of a typographic ligature for the trailing *st* character pair. There are at least three distinct reasons why this outcome is not desirable.

First, given the rather distinctive look of the *st* ligature, the word *stochastic* may look a bit odd if the *st* ligature is used only once—*stochastic*—simply because the *as* ligature is allowed to pre-empt the second *st* ligature; readers may prefer the look of *stochastic*. Second, non-use of the *st/st* ligature may be undesirable if the same word occurs twice and in close visual proximity, once set in the upright font shape—for which there are no ligatures for the *as*, *is*, and *us* character pairs and hence for which the issue of pre-emption of the *st* doesn't arise—and once in italics: *must* and *must*; readers may prefer the look of *must* and *must*. Or, consider the words “historian” and “history” when typesetting them in italics: I'd say it's much better to typeset them as *historian* and *history* rather than as *historian* and *history*. Similarly, I suspect that Austrians and Australians—at least the ones who care about discretionary typographic ligatures—may prefer to see the name of their country typeset as *Austria* and *Australia* rather than as *Austria* and *Australia*. Finally: Do you prefer the look of *Do fast festive fists foster fustiness?* or that of *Do fast festive fists foster fustiness?* You prefer the latter look too? Great!

Third, there may be cases where an *as* ligature not only pre-empts a subsequent *st* ligature but also spans a morpheme boundary, as in the words *astride*, *infrastructure*, and *seastrand*. For such words, the *as* ligature should probably be suppressed in any case to increase the words' legibility: *astride*, *infrastructure*, and *seastrand*.

The `selnolig` package is set to give preference to the distinctive-looking *st* ligature over *as*, *is*, and *us* ligatures. To this end, the following `\no1ig` rules are provided:²⁷

²⁶For the font Garamond Premier Pro, I've discovered the following peculiar exception to the general rule that T_EX always gives precedence to a ligature for the first two characters of a character triple: For the character triple *fis* (as in *fist* and *fish*), LuaT_EX gives preference to the trailing *is* ligature over the leading *fi* ligature, causing these words to be typeset as *fish* and *fist*, respectively. I can't tell if this is a conscious design feature or a bug in this font. The `selnolig` package overrides this behavior, i.e., it is set to give preference to the leading *fi* ligature over the trailing *is* ligature for words that contain the strings *fist* and *fish*; hence, they'll be typeset as *fish* and *fist*, respectively.

Note that if the `broadf` option is set, as is the case for the document you're currently reading, a side effect of this setting is that words such as *deafish*, *dwarfish*, *elfish*, *oafish*, *selfish*, *unselfish*, *wolfish*, *draffish*, *giraffish*, *gruffish*, *offish*, *raffish*, *sniffish*, *standoffish*, *stiffish*, and *toffish*, as well as the associated adverbs ending in *-ly*, will *not* feature an *is* ligature. This loss is, hopefully, not too serious.

²⁷The second of these three commands, while correct for most words that contain the string *ist*, unnecessarily suppresses the *is* ligature for words for which the *st* character pair crosses a morpheme boundary, e.g., words that start with *dis-t...*—e.g., *distend*, *distribute*, *distrust*, *disturb*—or with *mis-t...*—e.g., *mistake*, *mistranslate*, *mistype*. (Note that separate `\no1ig` rules already suppress the *st/st* ligature for these words.) At this time there are no plans to address this (overall hopefully minor?) issue.

```

\nolig{ast}{a|st}
\nolig{ist}{i|st}
\nolig{ust}{u|st}

```

Ligatures for *as*, *es*, *is*, and *us* that pre-empt an *ſ* ligature

The same three reasons for not letting *as*, *es*, *is*, and *us* ligatures pre-empt an *ſ* ligature also apply to the case of the equally distinctive-looking *ſ* ligature. The `selnolig` package therefore provides rules to ensure that the *ſ* ligature is used in words such as *claſſ*, *haſſ*, *raſſberry*, *teaſpoon*, *waſſ*, *eſpionage*, *hiſpanic*, *criſſ*, *liſſ*, *whiſſer*, and *cuſſ*.

Ligatures for *at* and *et* that pre-empt a *th* ligature

Suppose that a font provides ligatures for the *at*, *et*, and *th* character pairs. By T_EX’s rules for forming ligatures, without ſpecial intervention the word *mathematics* will be typeset as *mathematics* rather than as *mathematics* because the fiſt *at* ligature pre-empts the *th* ligature. The ſame happens for words ſuch as *bath*, *Kathryn*, and *pathology*. Given the commonneſs and the diſtinctive pronuciation of the *th* character pair in the English language, as well as the high frequency of this character pair in words of Greek origin (for which the Latin-alphabet *th* character pair derives from the ſingle Greek character *θ/ϑ*), it ſeems undeſirable to let the *at*-ligature pre-empt the *th* ligature for theſe words.

Fixing the *at*–*th* ligature pre-emption iſſue globally—e.g., via `\nolig{ath}{a|th}`—is not completely innocuous, though, becauſe doing ſo will alſo ſuppreſs the *at* ligature for words ſuch as *boathook*, for which the *th* ligature would ſpan a morpheme boundary and thus ſhouldn’t be employed anyway. For ſuch words, then, there’s no need to ſuppreſs the *at* ligature. Theſe caſes are dealt with by providing ſpecific `\keeplig` rules to re-enable the uſe of the *at* ligature.

Suppreſſing an *et* ligature in favor of a ſubſequent *th* ligature via `\nolig{eth}{e|th}` is almoſt univerſally correct, either becauſe the *th* ligature *ſhould* take precedence—as in the words *ethics*, *methane*, and *teeth*—or becauſe the *et* ligature would croſs a morpheme boundary and hence ſhouldn’t be uſed anyway, as in the words *forethought* and *rethink*. I ſay that it’s *almoſt* univerſally correct to do ſo; however, there are ſome words, ſuch as *Beethoven*, *prophethood*, and *sweetheart*, for which the *th* ligature would be inappropriate anyway and for which the uſe of the *et* ligature would hence be unproblematic. To addreſs this iſſue, `\keeplig` rules are provided to override the rule `\nolig{eth}{e|th}` for theſe words, ſo that they’ll get typeset as *Beethoven*, *prophethood*, and *sweetheart*.²⁸

Ligatures for *at* and *et* that pre-empt a *ta* ligature

There ſeem to be very few English words for which an *at* ligature might inappropriately pre-empt a *ta* ligature. One ſuch word is *atap*; its readability is likely enhanced if it’s typeset as *atap* rather than as *atap*.

Virtually all words for which an *et* ligature might inappropriately pre-empt the uſe of a trailing *ta* ligature appear to be words for which the *et* ligature croſſes a morpheme boundary and ſhould be ſuppreſſed.

²⁸Note that this method works if the font being uſed provides both *et* and *th* ligatures. If the text font you employ provides only a *th* ligature but no *et* ligature, theſe `\keeplig` rules ſhould be diſabled.

Examples are *betake*, *betatter*, *bristletail*, *caretaker*, *detach*, *dovetail*, *foretaste*, *pretax*, *retable*, *retack*, *retard*, *retarget*, *timetable*, and *wiretap*. The *et*-related ligature suppression rules already put in place to deal with morpheme boundary crossing cases should therefore suffice to catch these cases as well.

Do be on the lookout for cases of persons' names which include the string *eta* and for which the trailing *ta* ligature should not be pre-empted by the leading *et* ligature. For instance, the author of this package prefers to see his surname typeset as *Loretan* rather than as *Loretan...*

6 Further issues

6.1 Known bugs

I'm not sure if the following constitutes a bug or "merely" a case of incompatibility between L^AT_EX packages. The *selnolig* package does not interact well with the L^AT_EX packages *ngerman* and *german*. Fortunately, the *selnolig* package *does* interact nicely with the *babel* package if one of the options *ngerman*, *german*, *austrian*, *naustrian*, *swissgerman*, or *swiss* is set. Unless someone can convince me that using the *ngerman* or *german* packages is preferable to using the *babel* package, I probably won't bother addressing this incompatibility.

6.2 Supplementary hyphenation exception patterns

T_EX's hyphenation algorithms are widely acknowledged to be very good. However, for the English language case at least, it tends to miss quite a few permissible hyphenation points when dealing with words that end in *-f-ing*, *-f-ier*, *-f-iest*, *-f-less*, *-f-like*, etc. Hyphenation exception lists are provided in the files *selnolig-english-hyphex.sty* and *selnolig-german-hyphex.sty*, respectively, for English and German words.

The German-language hyphenation exception list is currently still the shorter of the two. The German word list is shorter in part because it is assumed that writers of German-language documents use the *babel* package and select the option *ngerman* (or one of the synonymous language options); doing so also loads specialized hyphenation patterns suitable for German texts.²⁹

It is possible to instruct *selnolig* *not* to load the package's hyphenation exception lists. You may want to do so, for instance, if you must use UK-English hyphenation patterns and therefore shouldn't use the US English-based hyphenation patterns provided by the package. (To the best of my knowledge, most of the hyphenation patterns employed in *selnolig-english-hyphex.sty* are common to UK and US English.) To skip loading the additional hyphenation patterns when invoking the *selnolig* package, you should specify the option *noadditionalhyphenationpatterns*. (I am obviously not trying to make it too easy to invoke this option ...)

As was already noted in [Section 2.3](#), if you use the *babel* package with, say, the *ngerman* option, be sure to load *selnolig* package *after* the *babel* package. That way, the *selnolig* package's additional hyphenation exception patterns won't be overridden by *babel*'s settings.

Incidentally, if the files *selnolig-english-hyphex.sty* and *selnolig-german-hyphex.sty* are located in a directory that's in the search path of your TeX distribution, these packages may be loaded via the usual `\usepackage` statements without having to load the entire *selnolig* package.

²⁹ As was already noted earlier, the *selnolig* package is also compatible with the *hyphsubst* and *polyglossia* packages.

6.3 How to track what the `selnolig` package is doing

If you execute the command `\debugon`, detailed information about each `\nolig` and `\keeplig` pattern match that is encountered is written to the `.log` file. Note that the default setting is `\debugoff`, i.e., the package’s activity is not recorded by default to the `.log` file.

Because of the redundancy built into some of the package’s `\nolig` commands, it is possible that more than one pattern match will occur for a given word. E.g., for the verb “auffahren”, two separate `\nolig` commands apply simultaneously, *viz.*, `\nolig{auff[aeiloruyäöü]}{auf|f}` and `\nolig{ffahr}{f|fahr}`. For this word, then, the following information is written to the `.log` file:

```
pattern match: auffahren - auff[aeiloruyäöü]
pattern match: auffahren - ffahr
Do ligature suppression for: auffahren
Inserting nlig whatsit before glyph: f
Last char: n
```

Some words contain more than one potential ligature suppression point. For example, if the word “Auflaufform”—which happens to have both an `fl`- and an `ff`-ligature that should be suppressed—is encountered, the following lines are written to the `.log` file; note that in this case, two separate `\nolig` commands “catch” the `fl` and `ff` ligatures:

```
pattern match: Auflaufform - flauf
pattern match: Auflaufform - Aufl[aeiouyäöü]
pattern match: Auflaufform - auff[aeiloruyäöü]
pattern match: Auflaufform - fform
Do ligature suppression for: Auflaufform
Inserting nlig whatsit before glyph: l
Inserting nlig whatsit before glyph: f
Last char: m
```

If *both* a `\nolig` and a `\keeplig` command apply to a word—as is the case for `fjord`, to which both `\nolig{fj}{f|j}` and `\keeplig{fjord}` apply—the following (mercifully short) bit of information is written to the `.log` file:

```
pattern match nlig and keeplig: fjord - fj - fjord
```

If more than one `\nolig` rule *as well as* a `\keeplig` rule apply to a given word, as is the case for the word “Streiflicht”, the following information is written to the `.log` file:

```
pattern match nlig and keeplig: Streiflicht - flich - flicht
pattern match: Streiflicht - reifl
Do ligature suppression for: Streiflicht
Inserting nlig whatsit before glyph: l
Last char: t
```

Observe that the first `nolig` rule’s pattern, `flich`, is overridden by the `keeplig` rule’s pattern `flicht`. The second `nolig` rule’s pattern, `reifl`, is *not* overridden, and it is the debugging-related information associated with the second `\nolig` rule that ends up being written to the `.log` file.

To terminate or suspend the writing of the debugging-related information to the `.log` file, execute the command `\debugoff`. To restart the logging of this information, issue the command `\debugon`.

6.4 Suspending and restarting the operation of `selnolig`’s macros

By default, `selnolig`’s macros are switched on (assuming, of course, that your document is compiled under `Lua \LaTeX`). If you want to suspend their operation, you should issue the command

```
\selnoligoff
```

at the desired point in your document. For instance, in this document the command `\selnoligoff` is issued at the start of the appendices. This is done because most of the material in the appendices (which contain mostly listings of `lua` and `\LaTeX` code) is typeset using a monospaced font for which all typographic ligatures have been disabled up front. Hence, there’s no need to disable any ligatures selectively in that part of the document, is there?

Conversely, if `selnolig`’s macros need to be switched back on, just issue the command

```
\selnoligon
```

In this document, this is done at that start of [Appendix E](#), which provides a long list of words found in *Die Buddenbrooks* for which `f`-ligatures should be suppressed.

6.5 Lists of words that fit German and English non-ligation patterns

Extensive lists of German and English language words for which one or more ligatures should be suppressed are provided in the supplemental files `selnolig-german-test.pdf` and `selnolig-english-test.pdf`. As was already mentioned in [Section 4.2](#), these documents may be viewed by opening a command window and typing `texdoc selnolig-german-test` and `texdoc selnolig-english-test`.

The list of words in `selnolig-german-test.pdf` consisted initially almost entirely of the words provided by the `rmligs` script. However, I’ve added quite a few more words to that list in the meantime. Thanks to the great work of Felix Lehmann and Steffen Hildebrand, explained in more detail in [Section 7](#), the package’s German language ligature-suppression rules now apply to a much larger set of words than what’s listed in `selnolig-german-test.pdf`. Naturally, suggestions for still more words to be de-ligated are always welcome.

6.6 Making suggestions and reporting bugs

Feedback on the `selnolig` package is always welcome, whether for making general suggestions, heaping praise on the package’s author, or for reporting bugs and other problems. [Emailing me](#) about `selnolig` will definitely get my attention. I’m also a fairly active participant (handle: “Mico”) on tex.stackexchange.com, and I occasionally check what goes on in [TeXwelt.de](https://www.texwelt.de), comp.text.tex and de.comp.text.tex. In case I appear to miss any `selnolig`-related discussions on these sites, please don’t hesitate to contact me to alert me to them.

When reporting what you believe to be shortcomings and/or mistakes with the package’s ligature suppression rules, please use a structure similar to the template given in [Appendix F](#) of this document.

If anyone is thinking of creating rules to suppress ligatures selectively for languages other than English and German and would like to make use of the “machinery” provided by the `selnolig` package, I’d be delighted to provide reasonable amounts of programming-related assistance.³⁰

The latest versions of all files that comprise the `selnolig` package may be found at the [package’s GitHub site](#). What’s there may be slightly more up to date than what I manage to push to the [CTAN page](#).

7 License and acknowledgments

The entire `selnolig` package is placed under the terms of the L^AT_EX Project Public License, version 1.3 or later (<http://www.latex-project.org/lppl.txt>). It has the status “maintained”.

I owe a huge intellectual and programming debt to Patrick Gundlach and Taco Hoekwater, who responded kindly and generously with detailed computer code to various queries I posted to tex.stackexchange.com.³¹ Without their help and support, this package would not exist. They certainly deserve most of the credit for the lua code used by the `selnolig` package.

Felix Lehmann (a linguist and expert in morphology, i.e., the study of morphemes) and Steffen Hildebrandt (computer scientist extraordinaire) served as patient and careful testers of several early beta versions of this package, uncovering and fixing bugs, pointing out unclear passages in the user guide, writing scripts to automate the discovery of redundancies and syntax errors in the package’s `\nolig` and `\keeplig` rules, and providing many excellent suggestions for improving the package. Steffen also provided crucial modifications to the package’s lua code to make possible the `\keeplig` and `\uselig` macros.

Equally importantly, Felix and Steffen created scripts to test systematically and comprehensively the package’s German `\nolig` and `\keeplig` rules for linguistic adequacy and (relative) completeness. They began with a corpus of almost 850 million [!] German words, which they marked up with information on the morphological constituents of each word. From this huge word list, they extracted a set of 462,000 unique word forms containing potential f-ligatures. According to their analysis, an early version (October 2012) of the `selnolig` package already dealt correctly with 85 percent (394,000) of those word forms, while still generating 21,000 Type I errors and 48,000 Type II errors!^{32,33}

Fortunately for me, they quickly discovered that a non-negligible part of the 69,000 errors wasn’t real but, rather, the result of spelling errors in the words included in the corpus and/or of suspect morphological analysis. Moreover, the detailed Type I and Type II error lists they generated were critical in helping me

³⁰A promising candidate (in my view at least) for getting the `selnolig` treatment would be `blackletter` or `Fraktur` fonts and their special ligatures. When used to write German documents, it is well known that these ligatures need to be suppressed for certain words, i.e., selectively. E.g., to suppress the `ß` (tz) ligature for the words `Brotzeit`, `Nachtzeit`, and `Satzzeit`, one could set up the rule `\nolig{tzeit}{t|zeit}`. If somebody wants to take on this project, I’d be happy to help you get started.

³¹See especially the questions [Any suggestions/requests for features for a new package that allows disabling ligatures for \(pre\)selected words?](#), [How to suppress the operation of a luatex-defined macro on a string if the string is part of macro or a label](#), and [Ligature suppression algorithm fails if the word in question contains an Umlaut \(dieresis\) before the ligature](#).

³²In the context of the `selnolig` package, a Type I error is the failure to suppress a typographically inappropriate ligature, and a Type II error is the improper suppression of a typographically appropriate ligature.

³³1,000 words contained more than one potential f-ligature, hence the difference.

refine—and occasionally revise completely—the package’s `\nolig` and `\keeplig` rules, rapidly bringing down the number of Type I and II errors. For instance, after Steffen wrote the lua code that made possible the `\keeplig` macro, the single rule `\keeplig{pflicht}` eliminated, in one fell swoop, more than 10,000 [really!] Type II errors generated by the package’s initial suppression of the fl-ligature in words that contain the morpheme `pflicht`. All major changes to the German language ligature suppression patterns are still being subjected to their testing algorithms, streamlining the tasks of detecting what’s left to improve and catching any newly introduced errors.

Felix and Steffen started the automated testing of the package’s `\nolig` and `\keeplig` rules as their finals project for the course *Introduction to Computational Linguistics* at the University of Massachusetts at Amherst which they attended in the fall of 2012.³⁴ They wish to thank the Institut für Maschinelle Sprachverarbeitung at the Universität Stuttgart for granting them a license for the morphological analysis tool SMOR³⁵ and, in particular, Helmut Schmid for his guidance. They also express their gratitude to the *Web-as-Corpus kool ynitiative* (WaCky) for letting them use the SDeWaC corpus,³⁶ as well as to Rajesh Bhatt (University of Massachusetts at Amherst), Miriam Butt (Universität Konstanz), and Sabine Schulte im Walde (Universität Stuttgart) for helping them find the right resources for their project.

The `rmligs` perl script by Björn Jacke lists about 1,700 German language words for which various f-ligatures should be suppressed. The initial set of German-language `\nolig` rules I wrote were designed to capture the words listed by `rmligs`.³⁷

Matthias Vogel very kindly shared with me a set of regular-expression based ligature suppressing macros, named *Ligatures-German*, he wrote for the WinEdt programmer’s editor. Matthias’s macros work by inserting babel-style “|” ligature-suppressing directives in the appropriate places in the .tex file, which can then be compiled with pdfL^AT_EX. These macros, and a file he sent me containing an extensive list of German words for which one or more f-ligatures should be suppressed, led me to thoroughly refine and extend the scope of the `selnolig` package’s German language ligature suppressing rules.

Barbara Beeton provided very detailed comments on an early version of the package’s user guide and its English language ligature suppression rules. She also noted that the readability of my surname might be enhanced if it were typeset as *Loretan* instead of as *Loretan*... David Bellows contacted me about the package and provided a suggestion that led me to extend some of the `\nolig` rules in Part 2 (activated by setting the option `broadf`) of the file `selnolig-english-patterns.sty`.

Other contributors who posted answers and comments to various ligature-related questions I’ve asked occasionally on tex.stackexchange.com and comp.text.tex, too numerous to name individually, also helped influence the genesis of this package. To all of you, I express my sincere thanks.

³⁴Both their [code](#) and their [finals paper](#) are available online.

B German-language ligature suppression rules: selnolig-german-patterns.sty

Introductory note: To accommodate the practice of Swiss-German writers of not using the “ß” character and using “ss” in its place, all search-and-insert strings that contain an “ß” character are duplicated with equivalent search-and-insert strings containing “ss”.

```
% !TeX root = selnolig.tex
% !TEX TS-program = lualatex

% (loretan dot mico at gmail dot com)

% A note on the organization of the \nolig
% macros in this file: They are grouped by
% the f-ligature being suppressed: ff -> f-f;
% fi -> f-i, fl -> f-l, etc. Within each of
% these sections, the \nolig commands are
% listed first for word-beginnings and
% second by word-interior search strings,
% alphabetically within each group.

% 1. ff -> f-f

E A case study: f-ligatures suppressed in Thomas Mann's *Die Buddenbrooks*

As noted in the introduction, in English language documents the suppression of ligatures that cross morpheme boundaries is generally not considered to be an urgent typographical priorities, quite possibly because words with ligatures that cross morpheme boundaries aren't all that common. I did a quick check of this claim by compiling Jack London's novels *Call of the Wild* and *The Sea Wolf*, obtained from Project Gutenberg's site in plain-text format, with *selnolig*. Sure enough, in *Call of the Wild* only one f-ligature is suppressed: the "fl" in wolflike/wolflike. In *The Sea Wolf*, again only one f-ligature is suppressed: the "ft" in fifth/fifth. Not exactly a lot of words, right?!

The situation is quite different for German texts. E.g., in Thomas Mann's novel *Die Buddenbrooks*, more than 440 words are caught by *selnolig*'s rules; they are listed below. Incidentally, the fi-ligature in the words Kaufinger and Kaufingerstraße is suppressed because "Kaufinger" ("chew-finger") looks unintentionally hilarious.

f-lig.	Words for which the f-lig. is suppressed by <i>selnolig</i> 's rules
fb, ffb	Aufbahrung, aufbegehrt, aufbegehrte, Aufbewahrungsort, Aufbietung, aufblicken, aufblitzenden, aufblitzt, aufblitzten, aufblühende, aufbrach, aufbrechen, aufbringen, aufbringt, Aufblick, Aufbrausen (2), Aufbruch (4), Briefbeschwerer, Dampfbrot, daraufbringen, greifbaren, Greifbares, heraufbefördert, hinaufblickte, Hofbräu, Hofbräuhaus (3), Hofbräuhaus, Kopfbewegung (3), Kopfbewegungen, Krippenaufbaus, Laufbahn, Privatbriefbogen, Scharfblick, Schiffbrüchen, Schlafbedürfnis, steifbeinigen, Stiefbruder (4), strafbar (2), tiefbelustigt, tiefblauen (2), unangreifbar
